BookMint Whitepaper

A decentralized publishing marketplace

1. Overview

BookMint is a set of Solidity contracts plus a static HTML/JS frontend using ethers.js. There is no backend, database or IPFS. Authors register books and sell access; readers pay in BOT or USDT; ownership and payments are recorded onchain.

2. Publishing

An author wallet creates a profile, then registers a book with title, description, category, language, cover reference, content reference, per-token prices and an optional royalty recipient. New books start as drafts; only the author can publish, unpublish, edit or reprice. Admin-set rules cap royalties and prices.

3. Access rights

A purchase increments an onchain access counter for (book, wallet). hasAccess(bookId, wallet) is the verification primitive. Each wallet may buy once unless the author enables repeat purchases. Access is a record of entitlement, not a technical lock on a file.

4. Payments and royalties

On purchase the buyer's tokens move into the contract. The platform fee (default 2.5%, capped at 10%) is credited to the admin; of the remainder, the royalty share goes to the royalty recipient and the rest to the author. Amounts are credited to internal balances, and recipients pull funds through withdraw(), which zeroes the balance before transfer and is reentrancy-guarded.

5. Moderation and administration

Anyone can report a listing once. The admin can pause a listing or the whole platform, set fees within the cap, and configure publishing rules. Admin power is centralized in one address; a multisig is recommended.

6. Storage limitations (disclosed)

Ebook bytes and cover images are not stored onchain; doing so is impractical and costly. BookMint stores metadata and a reference string supplied by the author. That reference is publicly readable by anyone inspecting contract storage, so it cannot gate content by itself. Referenced files may disappear or change, and BookMint cannot guarantee availability.

7. No DRM claim

BookMint does not and cannot prevent a buyer who has downloaded a file from copying or redistributing it. Onchain access records prove purchase, nothing more. Authors needing enforcement

must rely on off-platform licensing.

8. Security notes

Controls: author-only listing changes, duplicate-purchase prevention, pull-payment withdrawals, fee cap, nonReentrant. Assumptions: BOT and USDT are standard ERC-20 tokens without fee-on-transfer behavior and share the same decimals in the frontend. The contracts are unaudited and should be independently audited before mainnet use.
